

Multivariate kernel regression

- Nonparametric regression. Suppose that $(X_1, Y_1), \dots, (X_n, Y_n)$ are IID data and

$$Y_i = f(X_i) + \varepsilon_i \quad (1)$$

for $i = 1, \dots, n$, where $(\varepsilon_1, \dots, \varepsilon_n)$ is independent of $(X_1, \dots, X_n)$, $E(\varepsilon_1) = 0$ and $Var(\varepsilon_1) = \sigma^2$. The problem of interest is to estimate m based on $(X_1, Y_1), \dots, (X_n, Y_n)$.

- Kernel function on R^d . A kernel function k on R^d usually satisfies the usual constraints:

(a) $k \geq 0$.

(b) $\int k(s)ds = 1$.

(c) $\int s_j k(s_1, \dots, s_d) d(s_1, \dots, s_d) = 0$ for $j = 1, \dots, d$.

(d) $\int \|s\|^2 k(s) ds < \infty$, where $\|(s_1, \dots, s_d)\|^2 = \sum_{j=1}^d s_j^2$.

- Example of a kernel function on R^d . Let k_0 be the density for $N(0, 1)$. Define

$$k(x_1, \dots, x_d) = k_0(x_1) \cdots k_0(x_d) \quad (2)$$

for $(x_1, \dots, x_d) \in R^d$. Then k is a kernel function on R^d .

- Kernel regression estimator. Suppose that $(X_1, \dots, X_n)$ is a random sample and X_i takes values in R^d for $i = 1, \dots, n$.

The kernel regression estimator for $f(x)$ with kernel k (defined on R^d) and bandwidth vector $h = (h_1, \dots, h_d)$ is

$$\hat{f}(x) = \frac{\sum_{i=1}^n Y_i k\left(\frac{x - X_i}{h}\right)}{\sum_{i=1}^n k\left(\frac{x - X_i}{h}\right)}. \quad (3)$$

Here for two vectors $a = (a_1, \dots, a_d)$ and $b = (b_1, \dots, b_d)$, $a - b = (a_1 - b_1, \dots, a_d - b_d)$ and $a/b = (a_1/b_1, \dots, a_d/b_d)$.

- Monte Carlo integration. To evaluate $\int_{[0,1]^d} f(x_1, \dots, x_d) d(x_1, \dots, x_d)$, we can generate $U_1, \dots, U_L$ from the uniform distribution on $[0, 1]^d$ for a large L , and then use

$$\frac{1}{L} \sum_{j=1}^L f(U_j)$$

L to approximate $\int_{[0,1]^d} f(x_1, \dots, x_d) d(x_1, \dots, x_d)$.

- Exercise 1. Write a function `ker.est` using R with the following input and output:

Input:

* data matrix **X** whose i -th row is X_i ,

- * data vector $y = (Y_1, \dots, Y_n)$,
- * bandwidth vector h , and
- * evaluation point x_0 .

Output: the output `ker.est(X,y,h,x0)` is $\hat{f}(x_0)$ based on (3) with $x_0 = x_0$ and the kernel function = the function k in (2).

- Example 1. Let `ker.est` be the function in Exercise 1. We will compute the kernel estimator $\hat{f}$ with kernel k in (2) and bandwidth $h = (0.05, 0.05)$ based on the data generated below. We will plot the estimated regression function and compute the ISE.

Generate data as follows.

```
set.seed(1)
f <- function(x1,x2){ dnorm(x1-0.5, sd=0.2)*dnorm(x2-0.5, sd=0.2) }
n <- 1000
X <- matrix(runif(n*2), n,2)
y <- f(X[,1],X[,2]) + rnorm(n,sd=0.4)
```

Compute $\hat{f}(x_0, y_0)$ and plot $\hat{f}(x_0, y_0)$ and $f(x_0, y_0)$ for $(x_0, y_0) \in \{(x, y) : x \in \{1/21, 2/21, \dots, 20/21\}, y \in \{1/11, 2/11, \dots, 10/11\}\}$, and then compute the ISE.

```
h0=0.05
xlist <- (1:20)/21; ylist <- (1:10)/11
n1 <- length(xlist); n2 <- length(ylist)
zm <- matrix(0, n1, n2)
for (i in 1:n1){ for (j in 1:n2){ zm[i,j] <- f(xlist[i], ylist[j]) } }
f.persp <- persp(xlist, ylist, zm, theta=20)

for (i in 1:n1){
  xi <- xlist[i]
  fhat.xi <- rep(0, n2)
  for (j in 1:n2){
    fhat.xi[j] <- ker.est(X, y, rep(h0,2), c(xi,ylist[j]))
  }
  lines(trans3d(xi, ylist, fhat.xi, pmat=f.persp), col=2)
}

dif1 <- function(u, v){ (f(u,v)-ker.est(X, y, rep(h0,2), c(u,v)))^2 }
tem1 <- function(u){
  tem2 <- function(v){ dif1(u,v) }
  vtem2 <- Vectorize(tem2)
  return(integrate(vtem2, 0, 1)$value)
}
vtem1 <- Vectorize(tem1)
integrate(vtem1, 0,1)$value
```

```
#h0 = 0.05 => ISE: 0.009570552
```

- Compute the ISE for the univariate case.

```

#data generation
set.seed(1)
f <- function(x1){ dnorm(x1-0.5, sd=0.2) }
n <- 1000
X <- runif(n)
y <- f(X) + rnorm(n,sd=0.4)
curve(f, 0,1)

#compute estimated regression function values
h0=0.05
fhat.x <- rep(0, n1)
for (i in 1:n1){
  fhat.x[i] <- ker.est(X, y, h0, xlist[i])
}
lines(xlist, fhat.x, col=2)

#compute ISE
tem1 <- function(u){ (f(u)-ker.est(X, y, h0, u))^2 }
vtem1 <- Vectorize(tem1)
integrate(vtem1, 0,1)$value

#h0 = 0.05 => ISE:  0.002296325

```

Exercise 2. Generate data as follows.

```

set.seed(1)
f <- function(x){ dnorm(x1-0.5, sd=0.2) }
n <- 1000
X <- runif(n)
y <- f(X) + rnorm(n,sd=0.4)

```

Suppose that we use a modified kernel function for bias correction in (2) with $h = 0.05$. Find the ISE for the estimation of the regression function f . Do you think it is necessary to use a bias-correction kernel?
